Bureau 414C

Master 1 computer science – Semester 8
Description

*Reactive programming* is programming with asynchronous data streams:
- Asynchronous like `CompleteableFuture`.
- Data streams like `Stream`.
Outline

General Concepts

Reactive Streams

Main Libraries

Reactive Streams

Main Libraries

Summary and References
## Relation with Existing API

<table>
<thead>
<tr>
<th></th>
<th>single item</th>
<th>multiple items</th>
</tr>
</thead>
<tbody>
<tr>
<td>synchronous</td>
<td><strong>T</strong> data</td>
<td><strong>Stream&lt;T&gt;</strong> stream</td>
</tr>
<tr>
<td>asynchronous</td>
<td><strong>Compl.Future&lt;T&gt;</strong> fut</td>
<td><strong>Publisher&lt;T&gt;</strong> pub</td>
</tr>
</tbody>
</table>

- A future/promise is to a value as publishers are to iterables/collections.
- Reacting to the completion of multiple futures (asynchronously, without blocking operation).
This is a click event represented by some value, e.g., a string.

This is an error.

This indicates the stream has completed.
Publish/Subscribe Model

Publisher

Stream of data

Subscriber
Overflow Problem

- Too much *pressure* with push-based methods.
- Reactive programming is thus “pull-based” to control the pressure.
Asynchronous stream processing with non-blocking backpressure:
Other Characteristics

**Composable** chaining operations (like stream and completable future).

**Lazy evaluation** evaluated as late as possible (like stream).

**Asynchronous** non-blocking operations (like completable future).

**Reusable/Cacheable** results can be reused (like completable future).

**Push-based** the data source initiates the processing (pull-based for stream).

**Message passing** data producers exchange messages containing the data (no shared-memory mechanism).
History and Technological Context

- Kind of dataflow programming
- Also called FRP (Functional Reactive Programming): functional, no side effect, immutable state, pure function.
- Related to observer and iterator design patterns.
- Close to actor concurrency model.
Relation with Reactive Systems

- Reactive programming can be used to build a reactive system.
- The **Reactive Manifesto** states the features that must be offered by a reactive system: responsive, resilient, elastic, message-driven.
The system responds in a timely manner if at all possible. Responsiveness is the cornerstone of **usability**.

The system stays responsive in the face of **failure**.

The system stays responsive under **varying workload**. It can react to changes in the input rate by increasing or decreasing the resources allocated to service these inputs.

The system relies on **asynchronous message passing** to establish a boundary between components that ensures loose coupling, isolation, and location transparency.
Outline

General Concepts

Reactive Streams
Flow API (Java 9)
SubmissionPublisher
Implementation Example

Main Libraries

Summary and References
Main Interfaces

```java
interface Publisher<T> {
    void subscribe(Subscriber<T> subscriber);
}
interface Subscriber<T> {
    void onSubscribe(Subscription subscription);
    void onNext(T item);
    void onError(Throwable throwable);
    void onComplete();
}
interface Subscription {
    void request(long n);
    void cancel();
}
```
## Dual to Iterable

<table>
<thead>
<tr>
<th>Event</th>
<th>Iterable (pull)</th>
<th>Observable (push)</th>
</tr>
</thead>
<tbody>
<tr>
<td>retrieve data</td>
<td>T next()</td>
<td>onNext(T)</td>
</tr>
<tr>
<td>discover error</td>
<td>throws Exception</td>
<td>onError( Exception)</td>
</tr>
<tr>
<td>complete</td>
<td>!hasNext()</td>
<td>onCompleted()</td>
</tr>
</tbody>
</table>

General Concepts

Reactive Streams
  Flow API (Java 9)
  SubmissionPublisher
  Implementation Example

Main Libraries

Summary and References
Interface

Implementation of Flow.Publisher:

```
SubmissionPublisher()
SubmissionPublisher(Executor executor,
    int maxBufferCapacity);
CompletableFuture<Void> consume(Consumer<T> cons)
int submit(T item)
void close()
```
Example

```java
var pub = new SubmissionPublisher<Integer>();
pub.consume(System.out::println);
pub.submit(1);
```
Outline

General Concepts

Reactive Streams

Flow API (Java 9)
SubmissionPublisher
Implementation Example

Main Libraries

Summary and References
class CustomSub implements Subscriber<Integer> {
    private Subscription subscription;
    public void onSubscribe(Subscription subscription) {
        this.subscription = subscription;
        subscription.request(1); }
    public void onNext(Integer value) {
        System.out.println(value);
        subscription.request(1); } 
    public void onError(Throwable t) {
        System.err.println(t.getMessage()); }
    public void onComplete() {
        System.out.println("Done!"); }
}
Chaining SubmissionPublisher

```java
var pub1 = new SubmissionPublisher<Integer>();
var pub2 = new SubmissionPublisher<Integer>();
var pub3 = new SubmissionPublisher<Double>();
var pub4 = new SubmissionPublisher<Double>();
pub1.consume(x -> { pub2.submit(x * x); });
pub1.consume(x -> { pub3.submit(x / 2.); });
pub2.consume(x -> {
    System.out.println("Square is: " + x); });
pub3.consume(x -> { if (x > 2) pub4.submit(x); });
pub4.consume(x -> {
    System.out.println("Half (> 2) is: " + x); });
pub1.submit(3);
pub1.submit(5);
```
Outline

General Concepts

Reactive Streams

Main Libraries

Summary and References
Main Libraries

**RxJava** Reactive Extensions, Netflix (more than 50 different operations)

**Reactor** from Spring (equivalent to RxJava)

**Akka** actor model
RxJava Example

```java
Flowable<Integer> flow = Flowable.range(1, 5)
    .map(v -> v * v)
    .filter(v -> v % 3 == 0)
    .subscribe(System.out::println);
```

- Flowable implements Publisher.
- `subscribe` triggers the execution (as with terminal operations, lazy evaluation).
Marble Diagrams
Classical Operations

- **map**
- **allMatch**
- **true**
- **skip(1)**

- **reduce**
- **exists**
- **false**
- **true**

- **limit(2)**
Advanced Operations

Main Libraries

Louis-Claude Canon

MCP – Reactive Programming
Concurrency Source

- By default, the main thread performs all operations (blocking).
- The operation `subscribeOn` specifies how data processing can be processed concurrently.
- The operation at each stage can be performed asynchronously on a specific executor.
